## The Theory of Consumer Behavior

The principle assumption upon which the theory of consumer behavior and demand is built is: a consumer attempts to allocate his/her limited money income among available goods and services so as to maximize his/her utility (satisfaction).

## Theory of Consumer Behavior

$\square$ Useful for understanding the demand side of the market.
$\square$ Utility - amount of satisfaction derived from the consumption of a commodity ....measurement units $\Rightarrow$ utils

## Theories of Consumer Choice

## $\square$ Utility Concepts:

## The Cardinal Utility Theory (TUC)

- Utility is measurable in a cardinal sense
- cardinal utility - assumes that we can assign values for utility, (Jevons, Walras, and Marshall). E.g., derive 100 utils from eating a slice of pizza

## The Ordinal Utility Theory (TUO)

- Utility is measurable in an ordinal sense
- ordinal utility approach - does not assign values, instead works with a ranking of preferences. (Pareto, Hicks, Slutsky)

## The Cardinal Approach

Nineteenth century economists, such as Jevons, Menger and Walras, assumed that utility was measurable in a cardinal sense, which means that the difference between two measurement is itself numerically significant.

$$
\mathrm{U}_{\mathrm{X}}=f(\mathrm{X}), \mathrm{U}_{\mathrm{Y}}=f(\mathrm{Y}), \ldots \ldots
$$

Utility is maximized when:

$$
\mathrm{MU}_{\mathrm{X}} / \mathrm{MU}_{\mathrm{Y}}=\mathrm{P}_{\mathrm{X}} / \mathrm{P}_{\mathrm{Y}}
$$

## The Cardinal Approach

## $\square$ Total utility (TU) - the overall level of

 satisfaction derived from consuming a good or service$\square$ Marginal utility (MU) additional satisfaction that an individual derives from consuming an additional unit of a good or service. $\checkmark$ Formula :

$$
\begin{aligned}
M U= & \frac{\text { Change in total utility }}{\text { Change in quantity }} \\
= & \underline{\Delta \mathrm{TU}}
\end{aligned}
$$

## The Cardinal Approach

$\square$ Law of Diminishing Marginal Utility (Return) = As more and more of a good are consumed, the process of consumption will (at some point) yield smaller and smaller additions to utility
$\square$ When the total utility maximum, marginal utility $=0$
$\square$ When the total utility begins to decrease, the marginal utility $=$ negative (-ve)

## EXAMPLE

| Number <br> Purchased | Total <br> Utility | Marginal <br> Utility |
| :---: | :---: | :---: |
| $\mathbf{0}$ | $\mathbf{0}$ | 0 |
| $\mathbf{1}$ | $\mathbf{4}$ | 4 |
| $\mathbf{2}$ | $\mathbf{7}$ | 3 |
| $\mathbf{3}$ | $\mathbf{8}$ | 1 |
| $\mathbf{4}$ | $\mathbf{8}$ | 0 |
| $\mathbf{5}$ | $\mathbf{7}$ | -1 |

## The Cardinal Approach

$\square$ TU, in general, increases with Q
$\square$ At some point, TU can start falling with Q (see $\mathrm{Q}=5$ )
$\square$ If TU is increasing, MU >0
$\square$ From Q = 1 onwards, MU is declining $\Rightarrow$ principle of diminishing marginal utility $\Rightarrow$ As more and more of a good are consumed, the process of consumption will (at some point) yield smaller and smaller additions to utility

## Consumer Equilibrium

$\square$ So far, we have assumed that any amount of goods and services are always available for consumption
$\square$ In reality, consumers face constraints (income and prices):

- Limited consumers income or budget
- Goods can be obtained at a price

## Some simplifying assumptions

$\square$ Consumer's objective: to maximize his/her utility subject to income constraint
$\square 2$ goods (X, Y)
$\square$ Prices Px, Py are fixed
$\square$ Consumer's income (I) is given

## Consumer Equilibrium

$\square$ Marginal utility per price $\Rightarrow$ additional utility derived from spending the next price (RM) on the good
$\square \mathbf{M U}$ per $\mathbf{R M}=\underline{\mathbf{M U}}$ P

## Consumer Equilibrium

## $\square$ Optimizing condition:

$$
\frac{M U_{X}}{P_{X}}=\frac{M U_{Y}}{P_{Y}}
$$

$\square$ If

$\Rightarrow$ spend more on good $X$ and less of $Y$

## Numerical Illustration

| $\mathbf{Q}_{\mathrm{x}}$ | $\mathrm{TU}_{\mathrm{X}}$ | $\mathrm{MU}_{\mathrm{x}}$ | $\frac{\mathrm{MUx}}{\mathrm{P}_{\mathrm{x}}}$ | $\mathrm{Q}_{\mathrm{Y}}$ | $\mathrm{TU}_{\mathrm{Y}}$ | $\mathrm{MU}_{\mathrm{Y}}$ | $\underline{\mathrm{MU}_{\mathrm{Y}}}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 1 | 30 | 30 | 15 | 1 | 50 | 50 | 5 |
| 2 | 39 | 9 | 4.5 | 2 | 105 | 55 | 5.5 |
| 3 | 45 | 6 | 3 | 3 | 148 | 43 | 4.3 |
| 4 | 50 | 5 | 2.5 | 4 | 178 | 30 | 3 |
| 5 | 54 | 4 | 2 | 5 | 198 | 20 | 2 |
| 6 | 56 | 2 | 1 | 6 | 213 | 15 | 1.5 |

## Simple Illustration

$\square$ Suppose: $\quad \mathbf{X}=$ fishball
Y = fishcake
$\square$ Assume: $\mathrm{P}_{\mathrm{X}}=2$

$$
\mathrm{P}_{\mathrm{Y}}=10
$$

## Cont.

## $\square 2$ potential optimum positions

$\square$ Combination A: $\rightarrow \mathrm{X}=3$ and $\mathrm{Y}=4$
$-\mathrm{TU}=\mathrm{TU}_{\mathrm{X}}+\mathrm{TU}_{\mathrm{Y}}=45+178=223$
$\square$ Combination B: $\rightarrow \quad \mathrm{X}=5$ and $\mathrm{Y}=5$
$-\mathrm{TU}=\mathrm{TU}_{\mathrm{X}}+\mathrm{TU}_{\mathrm{Y}}=54+198=252$

## Cont.

$\square$ Presence of 2 potential equilibrium positions suggests that we need to consider income. To do so let us examine how much each consumer spends for each combination.
$\square$ Expenditure per combination

- Total expenditure $=P_{X} \mathbf{X}+\mathrm{P}_{\mathbf{Y}} \mathbf{Y}$
- Combination A: 3(2) + 4(10) = 46

Combination B: 5(2)+5(10)=60

## Cont.

## $\square$ Scenarios:

- If consumer's income $=46$, then the optimum is given by combination $\mathbf{A}$. ....Combination B is not affordable
- If the consumer's income $=60$, then the optimum is given by Combination B....Combination $\mathbf{A}$ is affordable but it yields a lower level of utility

## Thank You
